Higher Education Students’ Experience of Emergency Remote Teaching during the Covid-19 Pandemic in Relation to Self-Regulation and Positivity

MOJCA JURIŠEVIČ*, LANA LAVRIH1, AMELA LIŠIĆ3, NEŽA PODLOGAR4 and URŠKA ŽERAK4

The main objective of the present research was to explore students’ experiences of emergency remote teaching during the Covid-19 pandemic. Specifically, we were interested in how strategies for coping with an emergency situation, learning strategies and positivity relate to this experience. A total of 337 university students participated in the study. The data were collected with an online questionnaire. The results show that students used more adaptive coping strategies (positive reappraisal, acceptance and refocus on planning) and fewer maladaptive strategies (blaming others, catastrophising). Furthermore, students reported the frequent use of two self-regulated learning strategies, i.e., environment structuring and goal setting, and the less frequent use of task strategies. Self-regulation and positivity explained a total of 40% of the variance of the students’ experience during the pandemic. Important predictors for more constructive experience were the frequent use of goal setting and environment structuring strategies, more pronounced positivity, and less frequent use of the catastrophising coping strategy. The research findings contribute to a better understanding of students’ emergency remote teaching and learning experience during the pandemic and its correlates. Moreover, the findings could enable academic staff to focus on the essential elements when supporting students to cope with the pandemic.

Keywords: coping strategies, cognitive emotion regulation, learning strategies, positivity, pandemic

Ključne besede: strategije spoprijemanja, kognitivno uravnavanje čustev, učne strategije, pozitivnost, pandemija
Introduction

In March 2020, the onset of the Covid-19 pandemic led to the transfer of the learning setting from traditional to distance. This had an immense impact on the organisation of education worldwide and presented a major challenge for both educators and students, as it required active participation in the study process (e.g., higher motivation and increased engagement through the use of self-regulated learning strategies) and reimagining the structure and mode of the study process (Aristovnik et al., 2020; Carter et al., 2020; Hodges et al., 2020). Furthermore, most of the problems stemmed from a lack of planning, coordination and communication, which added to the stressfulness of the situation (Bozkurt et al., 2020; Browning et al., 2021). The most frequent challenges in higher education institutions were transferring the study process online, grading and evaluating students’ work, offering support to foreign exchange students, and mental health care of university staff and students (Sahu, 2020). At the University of Ljubljana in Slovenia, emergency remote teaching (ERT) began on 18 March 2020, in the middle of the fifth week of a 15-week semester. At that time, all forms of face-to-face instruction and contacts were cancelled, and the use of various online forms of educational activities and communication was recommended. These restrictions were modified slightly after the 11th week of the semester to allow for practical training and final exams at the university or off-campus facilities in smaller groups and under special circumstances.

Some students were negatively affected by studying in these extreme circumstances, reporting feelings of anxiety, uncertainty and stress (Mudenda et al., 2020). Among the listed disadvantages of ERT that induced these feelings were a lowered degree of self-efficacy and deterioration of academic integrity (Li, Cao et al., 2020). In order to avoid these mishaps in the future, universities should consider a better way of evaluating students’ work and leading the study process; specifically, they should focus on reducing unnecessary workload and increasing interaction between students and educators (Odriozola-González et al., 2020). Furthermore, the way the institution handles the situation and relays information to the students plays an especially important role in reassuring students and thus making the transition to ERT easier (Elmer et al., 2020; Li, Wang et al., 2020; Mechili et al., 2020; Mukhtar et al., 2020; Son et al., 2020; Wang et al., 2020). Students’ attitudes towards the situation matter as well. Positive thinking and resilience can reduce the negative effects that the situation might have on their mental wellbeing (Yang et al., 2020).

On the other hand, students mentioned some advantages of ERT; namely, the flexibility of the study process and the possibility to adapt it to their
needs (Mukhtar et al., 2020). Moreover, Hamza et al. (2020) reported that the situation regarding university students’ mental health was not as dire as some other studies reported, although a certain discomfort arose due to social isolation. This reinforces the need to pay special attention to students who may be at higher risk of mental health deterioration. In another study, Shawaqfeh et al. (2020) reported that the majority of students had a positive experience with ERT during the pandemic outbreak.

Based on the contemporary research findings, it can be assumed that possible factors influencing the experience of an extreme situation such as ERT during the pandemic are self-regulated learning, positivity and cognitive emotion regulation.

**Cognitive Emotion Regulation**

Emotions play an important role in the school setting and influence students’ learning (Efklides, 2011; Frenzel et al., 2009; Kesici & Erdogan, 2009; Pekrun et al., 2011; Turner & Husman, 2008). Emotion regulation is associated with students’ academic success and productivity (Bortoletto & Boruchovitch, 2013; DeCuir-Gunby et al., 2009; Pekrun et al., 2011). It is especially important in the academic context when individuals experience stressful events, as stress affects individuals’ performance, physical and mental health (Pascoe et al., 2020). Individuals who better self-regulate their emotions are more resilient despite experiencing stressful life events (Troy & Mauss, 2011; Tugade & Fredrickson, 2004).

The various cognitive emotion regulation strategies one can use in stressful situations are particularly important elements of emotion regulation. Positive-focused cognitive emotion regulation includes more adaptive cognitive strategies, such as positive refocusing, positive reappraisal, putting into perspective, refocus on planning, and acceptance. Negative-focused cognitive emotion regulation consists of less adaptive strategies, such as self-blame, rumination, catastrophising and blaming others (Extremera et al., 2020; Garnefski et al., 2001; Garnefski & Kraaij, 2006). Research findings have shown that the former are associated with greater psychological and subjective wellbeing, more positive emotions and better mental health (Extremera et al., 2020; Garnefski & Kraaij, 2006; Gross & John, 2003; Gustems-Carnicer & Calderón, 2013; Lee et al., 2016), whereas the latter are associated with problems in mental health and emotional functioning (Aldao et al., 2010; Amaral et al., 2015; Garnefski & Kraaij, 2006; Sullivan et al., 1995). In contrast, Jenaabadi et al. (2015) did not confirm the correlation between the use of specific emotional regulation strategies and mental health.
Self-Regulated Learning in Emergency Circumstances

Self-regulation strategies play a crucial role in academic success, cognition, social and adaptive functioning, and postponing instant gratification. They are among the most important human skills, as they enable adaptability in different situations (Eisenberg et al., 2004; Zimmerman, 2005). Zimmerman (2013) defines self-regulated learning (SRL) as a self-directed process in which students set their own learning goals, while monitoring, controlling and regulating their behaviour, motivation and cognition. It is a cyclical process in that the self-feedback from prior performance helps students adjust their future actions. According to the triadic loop of self-regulation, it is divided into behavioural, environmental and covert self-regulation (Zimmerman, 2005). A diverse set of SRL strategies allows students to cope with various situations and social contexts more effectively (Schunk & Greene, 2018).

Usher and Schunk (2018) claimed that environment, with its different micro- and macro-level environmental factors and stressors, can have an impact on students’ self-regulatory processes. From this perspective, the Covid-19 pandemic presents a specific environmental factor that has an important impact on students’ SRL and cognitive emotion regulation. Effective coping with a stressful situation includes the use of coping strategies that promote resilience (Beer & Moneta, 2012; Luthar et al., 2000). Turner and Husman (2008) revealed that SRL can facilitate college students’ self-regulation of emotions in stressful situations. SRL is especially important in extreme circumstances, as students are faced with new challenges and workload that influence their learning process and academic success (Bradley et al., 2017; Eom & Ashill, 2016).

In the distance education setting, students employ an array of different SRL strategies, such as environment structuring, goal setting, time management, help seeking, specific task strategies and self-evaluation (Barnard et al., 2009, Cleary et al., 2015; Karabenick & Newman, 2011; Seli & Dembo, 2020). Gonzales et al. (2020) investigated the performance of students in higher education before and after confinement due to the Covid-19 pandemic. Their findings suggest that the confinement had a significant positive effect in students’ performance, as they began studying on a more continuous basis (as opposed to before the outbreak) and thus improved their self-efficacy.

Positivity

Positivity is the tendency to view life and life experiences in a positive perspective (Caprara et al., 2012). Positive orientation is the basis of self-concept,
life satisfaction and optimism (Alessandri et al., 2012). Positivity in university students positively correlates with better general health (Jenaabadi et al., 2015), personality trait energy and emotional stability, and negatively correlates with depression (Caprara et al., 2012). The more positive students are, the more they are satisfied with the quality of college life (Tho et al., 2020). Students are also more academically and socially successful, as positivity enables them to perceive themselves as being able to cope with challenges in the academic context (Barbaranelli et al., 2019). Students who report greater optimism at the beginning of the first semester at university report smaller increases in stress and depression at the end of the first semester, which shows that optimism also supports better adjustment to stressful life events (Brissette et al., 2002).

**Aim of the Present Research**

The main aim of the present research was to determine the predictive value of students’ self-regulation and positivity for a better experience in the extreme situation of the Covid-19 pandemic. We posed three questions: How did students self-regulate during the Covid-19 pandemic in the spring semester of 2019/20? How were the students’ experiences of ERT during the Covid-19 pandemic associated with cognitive emotion regulation, SRL strategies and a positive attitude towards life? What were the important predictors of students’ constructive pandemic experience?

**Method**

**Participants**

The sample included 337 participants (92.6% female), all pre-service teachers at the Faculty of Education of the University of Ljubljana in the 2019/20 academic year (17.8% of the student population). Most of the students attended first-cycle study programmes (88.7%) and were fairly evenly distributed by year of study (i.e., 26.7% first-year students, 22.6% second-year students, 19.3% third-year students and 17.8% fourth-year students), but second-cycle students (9.4%) and part-time students (4.2%) were also among the participants. Most of the students were enrolled in Primary Education (26.1%), Special and Rehabilitation Pedagogy (19.0%), Two-Subject Teacher (18.4%) and Social Pedagogy (15.4%). Students from other majors were underrepresented. The age of the participants ranged from 19 to 29 years ($M = 21.61; SD = 1.82$). The students’ mean overall academic performance was relatively high, ranging from 6 to 10 ($M = 8.48; SD = .72$).
Instruments

In the present study, three instruments were used that had previously been translated into Slovenian using forward translation (see Brislin et al., 1973; Weeks et al., 2007).

The Cognitive Emotion Regulation Questionnaire – CERQ – short (Garnefski & Kraaij, 2006) is a short form of the longer version of the questionnaire (Garnefski et al., 2001). It measures the individual’s style of cognitive response to stressful events or the use of cognitive emotion regulation strategies in a particular stressful event or situation. It consists of nine scales with 18 items: Self-Blame, Blaming Others, Rumination, Catastrophising, Positive Refocusing, Refocus on Planning, Positive Reappraisal, Putting into Perspective, and Acceptance. The items are in a 5-point Likert response format (1 – almost never, 5 – almost always). We first confirmed an adequate fit of the model to the predicted factor structure ($\chi^2(99) = 185.60; \text{RMSEA} = .05; \text{CFI} = .96; \text{TLI} = .93$) and verified the acceptable reliability of the scales ($.61 < \alpha < .85$).

The Online Self-regulated Learning Questionnaire – OSLQ (Barnard et al., 2009) measures the use of self-regulation strategies in an online learning environment. It consists of six scales with 24 items: Goal Setting, Environment Structuring, Task Strategies, Time Management, Help Seeking, and Self-Evaluation. The items are in a 5-point Likert response format (1 – strongly disagree, 5 – strongly agree). We first confirmed an adequate fit of the model to the predicted factor structure ($\chi^2(174) = 434.54; \text{RMSEA} = .07; \text{CFI} = .89; \text{TLI} = .86$) and verified the acceptable reliability of the scales ($.65 < \alpha < .79$).

The Positivity Scale (Caprara et al., 2012) measures positivity, defined as an orientation to view oneself, one’s own life and the future in a positive perspective. It consists of 8 items, which are in a 5-point Likert response format (1 – strongly disagree, 5 – strongly agree). We first confirmed an adequate fit of the model to the predicted factor structure ($\chi^2(9) = 64.94; \text{RMSEA} = .14; \text{CFI} = .93; \text{TLI} = .88$) and verified the acceptable reliability of the scale ($\alpha = .85$).

The Pandemic Experience Questionnaire measures the experience of studying during the Covid-19 pandemic. It consists of eight items, four of which were adapted from Ristić Dedić (2020). They refer to trusting in one’s capabilities, emotional experience, level of energy and the ability to focus on studying during the Covid-19 pandemic. The other four items – about being adequately informed, trusting in completing study duties, negative thinking, and having the support of academic staff – were added for the purpose of this study. The response format is a 5-point Likert scale (1 – strongly disagree, 5 – strongly agree).
We first confirmed the one-factor structure of the questionnaire using exploratory data analysis (KMO = 0.86, Bartlett $p < .001$, one factor explains 44.6% of the variance) and verified the acceptable reliability of the scale ($\alpha = .84$).

**Procedures**

The data were collected over a three-week period from April to May in the spring semester of 2019/20 with an online questionnaire made in the Slovenian open source application 1KA. Participation was anonymous and voluntarily.

The data were analysed with IBM SPSS Statistics (version 22) and R (version 4.0.3). The main part of analysis was multiple regression (method Enter). Preliminary analyses showed that the assumptions for multiple regression were met: linear relationship, multivariate normality, homoscedasticity, and no multicollinearity ($1.11 < \text{VIF} < 2.21$).

**Results**

**Students’ Self-Regulation during the Covid-19 Pandemic**

Table 1 presents descriptive statistics for all of the included variables. The most used cognitive emotion self-regulation strategies were positive reappraisal (e.g., thinking about giving a positive meaning to the situation in terms of personal growth), acceptance (e.g., coming to terms with what had happened), and refocus on planning (e.g., thinking about what measures to take to deal with the situation), which are considered as adaptive strategies. The least used were less adaptive strategies, such as blaming others and catastrophising (e.g., a strong emphasis on fear about the situation). The third least used strategy was positive refocusing (e.g., thinking about other, pleasant matters instead of the actual situation). The most used academic self-regulation strategies during ERT were environment structuring (e.g., choosing a comfortable space without distractions) and goal setting (e.g., setting short- and long-term goals and standards). On the other hand, task strategies were the least used during ERT (e.g., preparation of more detailed notes and questions, performing additional tasks). On average, the students reported a positive outlook on life and the future, as well as a relatively constructive experience of the current situation of ERT during the pandemic.

The Relationship between Students’ Pandemic Experience and Cognitive Emotion Regulation, SRL Strategies and Positivity

The correlations between the included variables are presented in Table 2. Correlations between the CERQ subscales ranged between –.01 and .53. Low positive correlation was present between the use of self-blame strategies with rumination, catastrophising and refocus on planning; between the use of putting into perspective strategies with refocus on planning, positive reappraisal and positive refocusing; and between the use of positive reappraisal strategies with refocus on planning and acceptance. The highest positive correlation was between two less adaptive cognitive emotion strategies: catastrophising and rumination.

All OSLQ subscales correlated positively and statistically significantly, with a mean correlation coefficient of .38. The highest associations were found between time management, task strategies and goal setting, and between help seeking and self-evaluation.

Positivity statistically significantly correlated with the use of goal setting strategies during ERT and cognitive emotion regulation strategies such as catastrophising, positive reappraisal and refocus on planning. More frequent use of these strategies was associated with a more positive outlook towards life and the future, except for the use of the catastrophising strategy, which was negatively correlated with positivity.

A statistically significant moderate positive correlation was found between positivity and the experience of ERT during the Covid-19 pandemic. More use of goal setting strategies and less use of catastrophising strategies were associated with a more constructive Covid-19 experience. Other statistically significant but low positive correlations were with SRL strategies (i.e., environment structuring, help seeking, time management, task strategies) and cognitive emotion strategies (i.e., positive reappraisal, refocus on planning); a statistically significant low negative correlation was with the rumination coping strategy.

Predictors of Students’ Constructive Pandemic Experience

With multiple linear regression, the features of self-regulation and positivity that contribute to a more constructive experience of ERT in the exceptional situation of the Covid-19 pandemic were analysed. The results are shown in Table 3. Regression-diagnostic procedures confirmed that the model was appropriate \( F(10, 302) = 20.89; p < .001 \). Ten predictors explained 40% of the variance in pandemic experience \( R = .65; R^2_{\text{adjusted}} = .40 \). Goal setting, positivity, catastrophising and environment structuring statistically significantly influenced the overall experience of ERT during the Covid-19 pandemic. The probability of a more constructive experience is increased by the frequent use of goal setting and environment structuring strategies and is more pronounced positivity, while decreasing with the use of the catastrophising coping strategy.

Discussion

The first aim of the present research was to gain a better understanding of the characteristics of students’ cognitive emotion regulation and SRL during ERT in the Covid-19 pandemic. Control over emotions is influenced not only by self-regulatory behaviours, but also by the context in which the emotional experience occurs (de la Fuente, 2020). However, individuals who use
emotional regulation strategies respond more resiliently to stressful life events (Troy & Mauss, 2011; Tugade & Fredrickson, 2004). In general, the students in the present study use more adaptive coping strategies (e.g., positive reappraisal) and less maladaptive ones (e.g., blaming others), which suggests more positive-focused cognitive emotion regulation (Garnefski et al., 2001; Garnefski & Kraaij, 2006). This could help students to better cope with ERT during the pandemic, as better regulated students might be more resilient despite experiencing stressful events (Troy & Mauss, 2011; Tugade & Friedrickson, 2004). The students’ coping strategy of putting the negative situation into perspective, which is mainly aimed at reducing the seriousness of the situation or emphasising its relativity, was associated with the use of other more adaptive cognitive emotion strategies. This implies that students should acknowledge negative aspects of ERT during a pandemic, but that they need support to further implement more adaptive cognitive emotion regulation strategies to change their perspective on these aspects (e.g., acceptance, refocus on planning, positive reappraisal). Consequently, they might experience more positive emotions, which could have a positive impact on learning in the distance education setting (D’Errico et al., 2018).

Regarding SRL strategies, the results show that students most often turned to environmental structuring and goal setting, which emphasises the importance of structured study and the living environment, and of setting achievable short- and long-term goals in remote education during stressful situations. Task strategies were used the least, suggesting that students spent more time and energy planning their study process and structuring the appropriate study environment than they did on actual assignments and study tasks. The change from face-to-face study to remote study was sudden, unexpected and never experienced before, which may explain why students felt the need to address these problems first in order to successfully tackle the actual study material (see also Biwer et al., 2021).

In the present study, students’ general positive orientation towards life and the future correlated positively with use of positive reappraisal and refocusing on planning, and correlated negatively with catastrophising, which implies that overall positivity correlated with the frequent use of more adaptive strategies and the less frequent use of less adaptive strategies. Similarly, Carver et al. (1989) found that the use of emotion regulation strategies in general stressful situations correlated positively with optimism and perceived control over the stressor.

In addition, we assessed the predictive value of these characteristics for a more constructive experience of the emergency situation of distance learning during the pandemic. As many researchers note, the pandemic led to changed
living and study conditions (Carter et al., 2020; Sahu, 2020), which could influence the experience of negative emotions (Bozkurt et al., 2020; Mudenda et al., 2020). The use of adaptive coping strategies (Troy & Mauss, 2011; Tugade & Fredrickson, 2004) and different SRL strategies (Bradley et al., 2017; Eom & Ashill, 2016), in addition to a more positive outlook on life (Brisette et al., 2002; Yang et al., 2020), could contribute to adaptability and a more constructive experience of the completely new situation (Tenney et al., 2016). This was also confirmed in the present study. The important predictors of a constructive experience of the pandemic and ERT were more frequent use of goal setting and environment structuring SRL strategies, a more positive outlook on life, and less frequent use of the catastrophising coping strategy. Goal setting strategies might have helped students to cope with the situation in a more effective manner, since most of the problems other students faced in a similar situation stemmed from lack of planning, coordination and communication (Bozkurt et al., 2020). Since the online learning environment provides students with more autonomy, a particularly important SRL strategy is environment structuring (Barnard et al., 2009). Students who lack the skills to organise the time and place for studying may have difficulty avoiding various distractions (e.g., social media, texting, television), which can negatively affect students’ experience with ERT and their academic performance. Catastrophising positively correlated with rumination, self-blame and blaming others, and negatively correlated with positive reappraisal. This could mean that students who focused on horrific and other negative aspects of ERT during the pandemic were also more focused on thinking about their emotional and cognitive experience of the situation and on putting blame on themselves and others, and less focused on positive aspects of the event. This is in line with other research that included students or the general population: findings show that the use of maladaptive strategies was associated with lower adaptation ability, a more stressful perception of the situation, and higher levels of emotional problems, depression and anxiety (Garnefski & Kraaij, 2006; Sullivan et al., 1995). The third important predictor of a more constructive experience of ERT during the pandemic was positivity, which was also associated with use of positive reappraisal and refocus on planning, and negatively associated with catastrophising, which means that a general positive outlook correlated with frequent use of more adaptive strategies and less frequent use of less adaptive ones. This is in line with other studies that suggest positivity strengthens students’ academic self-efficacy (Barbaranelli et al., 2019) and supports adjustment to stressful events (Brissette et al., 2002).
Conclusion

The results of the present study provide further insight into students’ experiences of ERT during the Covid-19 pandemic. Specifically, they imply that students who successfully met the challenges of ERT were more likely to use goal-setting and environment structuring strategies, were generally more positive about life, and were less likely to use the catastrophising coping strategy.

These results must nevertheless be interpreted with caution, particularly due to the online data collection and the associated sample selection. Despite the advantages of an online survey during lockdown, the validity of the results and their generalisability might remain questionable (Wright, 2005); specifically, the recruited students, who were predominately female, represented approximately 17% of the population and were high-achieving students on average. One might therefore assume that they are more conscientious and regulate their learning better; on the other hand, we lack information about the 83% of students who are probably not so. Moreover, when discussing the results of this study it is important to keep in mind that we do not have a direct comparison with the measured variables before the pandemic.

Implications for further research may therefore arise from the presented facts, addressing both methodological and contextual variables, such as focusing on individual differences between students, as well as replication of the survey and longitudinal monitoring of students’ lived experiences during the next waves of the Covid-19 pandemic and beyond.

Finally, we must not overlook the important role of academic staff, who need to be aware of the various factors that influence ERT (Bozkurt et al., 2020) and adapt their teaching methods to successfully support and guide students in the learning process. A supportive ERT environment includes regular electronic communication with students about subject content and goals, monitoring students’ use of learning strategies, providing consistent support and formative feedback on students’ progress, and modelling and encouraging students to use appropriate learning and coping strategies (Wandler & Imbriale, 2017). In addition, it is important to help students learn and apply metacognitive learning strategies, such as planning or adapting learning goals, which are particularly valuable in emergency situations with weak external structure and guidance (Dabbagh & Kitsantas, 2004). Overall, this provides a reasonable starting point for examining the quality of higher education organisation in emergencies through the systematic promotion of student self-regulation in learning (Rasheed et al., 2020; Tuckman & Kennedy, 2011).

Biographical note

**Moja Jurišević**, PhD, is a full professor of educational psychology at the Faculty of Education, University of Ljubljana, Slovenia. Her main research interests are motivation to learn, psychosocial development of students, professional development of teachers, and studies of giftedness and gifted education.

**Lana Lavrih** is a student of undergraduate programs of special and rehabilitation pedagogy (Faculty of Education) and translation (Faculty of Arts) at University of Ljubljana. Her interests include areas of neurodevelopmental disorders (especially specific learning disabilities), foreign languages (English, French and Slovene sign language) and multilingualism in children with special needs in early education.

**Amela Lišić** is a graduate of Special and Rehabilitation Pedagogy at the Faculty of Education, University of Ljubljana. Her main research and working interests are neurodevelopmental disorders (mainly ASD) and effective strategies for their treatment. Her other research interests are self-regulated learning, inclusion, development of self-advocacy of students with special needs and environmental influences on the development of children with special needs.

**Neža Podlogar**, MSc, is a teaching assistant in the field of educational psychology at the Faculty of Education, University of Ljubljana, Slovenia and PhD student at the Faculty of Arts, University of Ljubljana, Slovenia. Her research interests focus on psychological aspects of gifted education, video game impact on cognition and intelligence.

**Urška Žerak** is a teaching assistant of educational psychology at the Faculty of Education of the University of Ljubljana. She is a PhD student in Applied Psychological Studies at the Faculty of Arts of the University of Ljubljana. Her research interests are in the field of self-regulated learning, learning strategies, gifted education, and teachers’ professional development. She is a member of Centre for Research and Promotion of Giftedness at the Faculty of Education University of Ljubljana and Slovenian Psychologists’ Association.
